(4-4) Streams and File Processing in C++

Instructor - Andrew S. O'Fallon CptS 122 (June 27, 2024) Washington State University

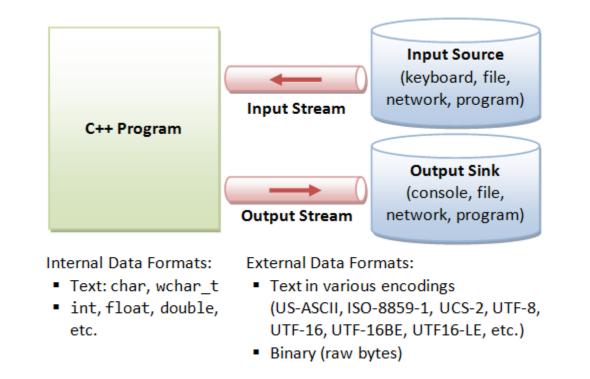

What is a Stream? A Refined Definition

- A sequence of objects (generally just considered bytes) that flow from a device to memory or from memory to a device
- For *input* operations, the bytes flow from the device (i.e. keyboard, network connection, disk, etc.) to main memory
- For *output* operations, the bytes flow from main menu to the device (screen, printer, etc.)

Abstraction of a Stream

3

Analogy for a Stream

- A conveyer belt
 - You can place an item in sequence on the belt,
 i.e. into the stream (insertion or output operation)
 - You can remove an item in sequence from the belt, i.e. take from the stream (extraction or input operation)

Classic Streams vs. Standard Streams

- The *classic* input/output streams for C++ supported byte-sized chars, which represented the ASCII characters
- Many alphabets require *more* characters than can be represented by a *byte* and the ASCII character set does not provide the characters
 - The Unicode character set provides these ones
- C++ provides standard stream libraries to process Unicode characters (wchar_t)

Standard Streams in C++ (1)

- For standard input/output streams, include <iostream>
 - cin is a predefined object of class istream and is connected to the standard input device (i.e. keyboard)
 - cin >> var // cin applying stream extraction operator - stops at whitespace for strings
 - cout is a predefined object of class ostream and is connected to the standard output device (i.e. screen)
 - cout << var // cout applying stream insertion operator

6

Standard Streams in C++ (2)

- Member function getline() will read a line from the stream
 - Inserts a null character at the end of the array of characters, removes and discards the '\n' from the stream (i.e. stored as a C string)

Recall the File Processing Algorithm!

- Step 1: open the desired file
 - Opening is based on filename and permissions (read, write, or append)
 - Associates a file with a stream
- Step 2: process the file
 - Read data from the file
 - Does not affect file
 - Write data to the file
 - Completely overwrites existing file
 - Add data to the end of the file
 - Retains previous information in file
- Step 3: close the file
 - Disassociates a file from a stream

8

Files Streams in C++ (1)

- For input/output streams to work with files, include <fstream>
 - ifstream objects enable input from a file
 - ofstream objects enable output to a file
 - fstream objects for input from and output to a file
- Associate file with a file stream either during construction (applying the constructor or by calling open())
 - fstream fstr("filename.txt") // an instantiation of fstream object Or fstr.open("filename.txt") // after instantiation

A. O'Fallon, J. Hagemeister

Files Streams in C++ (2)

• Read from files using:

- fstr >> var; // applying the stream
 extraction operator stops at whitespace
 for strings
- fstr.getline () // to read entire line into a character array
 - Stored as a C string
- Write to files using:
 - fstr << var; // applying the stream
 insertion operator</pre>

Files Streams in C++ (3)

- Each file ends with an end-of-file marker (EOF)
 check if at end of file using fstr.eof()
- Close a file using:
 - fstr.close();

Closing Thoughts on Files

- Files are required for many applications
- Files may be created and manipulated in any manner appropriate for an application
