## **Intel 80x86 Instruction Set Summary**

This document contains a description of all 80x86 instructions not including math coprocessor instructions. Each instruction is described briefly. All operand forms valid with each instruction are shown and some syntax examples are given. The flags affected by each instruction are shown in the upper right corner for the description for the instruction. The effect of instructions on the flags are indicated as follows:

- No change
- ? Unpredictable change
- \* Predictable change
- 1 Set to 1
- 0 Set to 0

AAA	ASCII adjust AX after addition	0 D I T S Z A P C ? ? ? * ? *
addition has occurre ASCII digit in AL, ex	sed to adjust the value in AL into the correct range aft ed. After executing an ADD or ADC instruction that lea recute AAA to produce a valid BCD result. dicates that a decimal overflow occurred, the BCD dig cremented.	aves a single BCD or
Example	Function	
AAA	Corrects the result of an ASCII addition	

AAD	ASCII adjust AX before division	0 D I T S Z A P C ? * * ? * ?
Description:		
This instruction is used before BCD division. Before execution, the AL register should contain a single unpacked BCD digit. The AH register should hold the next higher order BCD digit. After executing the AAD instruction, AX contains the binary equivalent of the two BCD digits.		
Example Function		
AAD	Corrects AX before an ASCII division	

AAM	ASCII adjust AX after multiplication	0 D I T S Z A P C ? * * ? * ?
<b>Description</b> : The AAM instruction converts the result of a single digit BCD multiplication in the AX register into two unpacked BCD digits. The high order digit will be in AH and the low order digit in AL.		
Example Function		
AAM	Corrects AX after an ASCII multiplication	

AAS	ASCII adjust AX after subtraction	0 D I T S Z A P C ? ? ? * ? *
SUB or SBB instruction	res that a BCD subtraction results in a valid BCD dig on that leaves a single BCD digit in AL, execute AAS duces a decimal borrow, the BCD is forced into the l	S to produce a valid
Example	Function	
AAD	Corrects AX after an ASCII subtraction	

ADC	Add with carry	0 D I T S Z A P C * * * * * *	
Description:			
This instruction adds the	This instruction adds the contents of the source and destination together, increments the result if		
the carry flag is set and s	stores the result in the destination. The operation	ands must be the same size.	
If the operands are signed	ed integers, OF flag will indicate an invalid re	esult. If the operands are	
unsigned, the CF will be	set if a carry occurred out of the high bit of t	the result.	
General Forms	Function		
ADC reg,idata	Add <i>idata</i> with carry to reg		
ADC mem,idata	Add <i>idata</i> with carry to memory location	mem	
ADC regd, regs	Add regs with carry to regd		
ADC reg,mem	Add contents of memory location memory	with carry to <i>reg</i>	
ADC mem,reg	Add contents of reg with carry to memor	ry location <i>mem</i>	
Examples			
ADC AL,BL	Adds BL with carry to AL		
ADC DATA1,AX	Adds AX with carry to memory location		
ADC BL,[DI]	Adds memory location DS:DI with carry	to BL	
ADC EAX,1	Adds 1 with carry to EAX		
ADC BYTE PTR [BX],2			

ADD	Add	0 D I T S Z A P C * * * * * *
Description:		
This instruction adds the co	ontents of the source and destination and store	s the result in the
destination. The operands	must be the same size. If the operands are sign	ned integers, the OF
flag indicates an invalid res	sult. If the operands are unsigned, the CF flag i	ndicates a carry out of
the high bit of the result. If	the operands are BCD digits, the AF flag indica	ates a decimal carry.
General Forms	Function	
ADD reg,idata	Add <i>idata</i> to reg	
ADD mem,idata	Add <i>idata</i> to memory location mem	
ADD regd, regs	Add regs to regd	
ADD reg,mem	Add contents of memory location mem to rec	9
ADD mem,reg	Add contents of reg to memory location mem	1
Examples	Function	
ADD CL,BL	Adds BL to CL	
ADD DATA2,DL	Adds DL to memory location DS:DATA2	
ADD CL,[SI]	Adds contents of memory location DS:SI to C	CL
ADD ECX,1	Adds 1 to ECX	
ADD WORD PTR [BX],2	Adds 2 to word in memory location DS:BX	

AND	Logical AND	O D I T S Z A P C 0 * * ? * 0	
Description:			
This instruction performs	This instruction performs a bit by bit logical AND operation on the contents of the source and		
destination, and stores the	e result in the destination.		
General Forms	Function		
AND reg,idata	Logical AND reg with idata		
AND mem,idata	Logical AND contents of memory location	<i>mem</i> with <i>idata</i>	
AND regd, regs	Logical AND regd with regs		
AND reg,mem	Logical AND reg with contents of memory location mem		
AND mem,reg	Logical AND contents of memory location	Logical AND contents of memory location mem with reg	
Examples			
AND AL,07FH	Clears the high order bit of AL		
AND DATA3,DX	Logical AND of word at memory location D	DS:DATA3 with DX	
AND CL,ES:[DI+2]	Logical AND of byte at memory location ES:DI+2 with CL		
AND BX,CX	Logical AND of BX with CX		
AND AX,MASK[SI]	Logical AND of word at memory location D	DS:MASK+SI with AX	

ARPL	Adjust requested privilege levelO D I T S Z A P(80286 or later) *	C -
Description:		
This instruction is used to modify a selector's requested privilege level. Both the source and destination operands must be valid selectors. If the RPL of the destination operand is numerically less (higher privilege level) than that of the		
source operand, the destination selector's RPL is changed to match that of the source operand, and ZF is set to 1. If the destination operand is numerically higher (less privileged), then it is not modified and ZF is set to 0.		
General Forms	Function	
ARPL regd, regs	Adjust RPL of regd down to agree with regs	
ARPL mem, reg	Adjust RPL of selector in location mem down to agree with reg	
Examples		
ARPL AX,BX	Privilege level of selector in AX adjusted to agree with BX	
ARPL MEM,CX	Privilege level of selector in DS:MEM adjusted to agree with CX	

BOUND	Check array bounds (80186 or later)	0 D I T S Z A P C 
Description:		
The source operand specifies the location of a memory table giving the array bounds (lower bound, followed by upper bound). The destination operand is an array index. If the source operand is not within the bounds specified by the destination operand, then an INT 5 is executed.		
General Forms	Function	
BOUND reg,mem	Check that array index in <i>reg</i> is within limits specified at <i>mem</i>	
Example		
BOUND AX, BETS	If AX is not in bounds of DS:BETS iss	sue INT 5 exception

BSF	Bit scan forward         O D I T S Z A P C           (80386 or later)	
Description:		
This instruction scans the source operand starting at bit position 0. It writes the bit position of the first 1 bit found to the destination operand. If the source operand is 0, the zero flag is set and the contents of the destination operand are undefined.		
General Forms	Function	
BSF regd, regs	Scan regd for 1 bit. Regs gets index of first 1 bit	
BSF reg,mem	Scan memory location <i>mem</i> for 1 bit. <i>Reg</i> gets index of first 1 bit	
Examples		
BSF AX,BX	Scans BX from bit 0, AX gets the position of the first 1 bit in BX, the	
BSF EAX,DAN	Z flag set if no bits in BX are set Scans DWORD at DS:DAN from bit 0, EAX gets the position of the first 1 bit, Z flag set if no bits in DS:DAN are set.	

BSR	Bit scan reverse (80386 or later)	0 D I T S Z A P C *
Description:		
This instruction scans the source operand starting at the highest bit position. It writes the bit position of the first 1 bit found to the destination operand. If the source operand is 0, the zero flag is set and the contents of the destination operand are undefined.		
General Forms	Function	
BSR regd,regs	Scan regd for 1 bit. Regs gets index of first 1 b	
BSR reg,mem	Scan memory location mem for 1 bit. Reg gets	index of first 1 bit
Examples		
BSR AX,BX	Scans BX from bit 15, AX gets the position of the Z flag set if no bits in BX are set.	he first 1 bit in BX, the
BSR EAX,MEM	Scans DWORD at DS:MEM from bit 31, EAX g first 1 bit, the Z flag is set if no bits in DS:MEM	

BSWAP	Byte swap (80486 or later)	0 D I T S Z A P C 
Description:		
This instruction converts the value in the specified 32 bit register from little endian format to big endian format. Byte 0 and byte 3 are exchanged, and byte 1 and byte 2 are exchanged.		
General Forms	Function	
BSWAP reg32	Swap the byte order of the specified register	
Example	· · · · · ·	
BSWAP EAX	Converts EAX from little-endian to big-endian format	

BT	Bit test	ODITSZAPC *
	(80386 or later)	*
Description:		
This instruction tests the bi	t specified by the operands and places its value	e into the carry flag. The
source operand contains a	n index into the bit array specified by the destin	nation. The state of the
specified bit is copied into	he carry flag.	
This instruction does not ad	ccept BYTE operands. It works only on 16 or 3	2 bit values. Do not use
	priented memory mapped i/o registers.	
General Forms	Function	
BT reg,idata	Copy the bit specified by idata from reg to th	e carry flag
BT mem,idata	Copy the bit specified by idata from memory	location mem to CF
BT regd,regs	Copy the bit specified by regs from regd to the	ne carry flag
BT mem,reg	Copy the bit specified by reg from memory lo	ocation mem to CF
Examples		
BT EBX,4	Test bit 4 of EBX, C <= bit 4	
BT MEM,1	Test bit 1 of memory location DS:MEM, C <=	= bit 1
BT EBX,ECX	Test bit ECX of EBX, C <= bit ECX	
BT MEM,AX	Test bit AX of memory location DS:MEM, C	<= bit AX

BTC	Bit test and complementO D I T S Z A P C(80386 or later) *	
Description:		
This instruction tests the bit specified by the operands and places its value into the carry flag. The specified bit is then complemented. The source operand contains an index into the bit array specified by the destination operand. The state of the selected bit is copied to the carry flag, and the bit is complemented. The carry flag will contain the state of the bit before it is complemented. This instruction does not work on byte operands. It can only be used on 16 or 32 bit operands. Do not use this instruction with memory mapped i/o devices that are 8 bits wide.		
General Forms	Function	
BTC reg,idata		
BTC mem,idata		
BTC regd, regs		
BTC mem,reg		
Examples		
BTC EBX,4	Test and complement bit 4 of EBX, C <= bit 4	
BTC MEM,1	Test and complement bit 1 or EBX, C <= bit 1	
BTC EBX,ECX	Test and complement bit ECX of EBX, C <= bit ECX	
BTC MEM,AX	Test and complement bit AX of location DS:MEM, C <= bit AX	

BTR	Bit test and reset (80386 or later)	0 D I T S Z A P C *
Description:	()	
This instruction tests the bit specified by the operands and places its value into the carry flag. The selected bit is then reset. The source operand contains an index into the bit array specified by the destination operand. The state of the selected bit is copied to the carry flag, and the bit is then reset. The carry flag will contain the state of the bit before it is reset. This instruction does not work on byte operands. It can only be used on 16 or 32 bit operands. Do not use this instruction with memory mapped i/o devices that are 8 bits wide.		
General Forms	Function	
BTR reg,idata		
BTR mem,idata		
BTR regd, regs		
BTR mem,reg		
Examples		
BTR EBX,4	Test and reset bit 4 of EBX, C <= bit 4	
BTR MEM,1	Test and reset bit 1 or EBX, C <= bit 1	
BTR EBX,ECX	Test and reset bit ECX of EBX, C <= bit ECX	
BTR MEM,AX	Test and reset bit AX of location DS:MEM, C	<= bit AX

BTS	Bit test and set (80386 or later)	0 D I T S Z A P C *	
<b>Description</b> : This instruction tests the bit	t specified by the operands then places its val	ue into the carry flag.	
The selected bit is then set	. The source operand contains the index of the	e bit array specified by	
then set. The carry flag will	he state of the selected bit is copied to the carr contain the state of the bit before it is set. Thi	s instruction does not	
	work on byte operands. It can only be used on 16 or 32 bit operands. Do not use this instruction with memory mapped i/o devices that are 8 bits wide.		
General Forms	Function		
BTS reg,idata			
BTS mem,idata			
BTS regd, regs			
BTS mem,reg			
Examples			
BTS EBX,4	Test and set bit 4 of EBX, C <= bit 4		
BTS MEM,1	Test and set bit 1 or EBX, C <= bit 1		
BTS EBX,ECX	Test and set bit ECX of EBX, C <= bit ECX		
BTS MEM,AX	Test and set bit AX of location DS:MEM, C <	<= bit AX	

CALL	Call far procedure (subroutine)	
<b>Description</b> : The far procedure call saves the current code segment selector and the address of the next instruction (IP or EIP) onto the stack. Control then transfers to the destination specified by the		
operand.	the stack. Control their transfers to the destination specified by the	
General Forms	Function	
CALL idata	Push CS:IP and then load CS:IP with value specified in idata	
CALLI mem	Push CS:IP and then load CS:IP with value contained in mem	
Examples		
CALL SUBR1	Call procedure SUBR1	
CALL FAR PTR JTAB[SI]	Call the procedure whose address is stored in memory location DS:[JTAB+SI]	
CALL MEM	Call FAR to the procedure whose address is stored in memory location DS:MEM. This assumes that MEM is declared as a DWORD	

CALL	Call near procedure (subroutine)	
Description:		
The near procedure call pu	shes the address of the next instruction (IP or EIP) onto the stack and	
then transfers control to the	e location specified by the operand. If the operand is an immediate	
value, the destination is rel	ative to the current location. If the operand is a memory address or	
register, the subroutine add	Iress is taken indirectly from the operand.	
General Forms	Function	
CALL offset	Push IP and then add offset to IP	
CALL mem	Push IP and then load IP with the contents of mem	
CALL reg	Push IP and then load IP with the contents of reg	
Examples		
CALL SUBR1	Call procedure SUBR1	
CALL CX	Call procedure whose address is in CX	
CALL NEAR PTR	Call NEAR to the procedure whose address is stored in memory	
JTAB[SI]	location DS:[JTAB+SI]	
CALL MEM	Call NEAR to the procedure whose address is stored in memory	
	location DS:MEM. This assumes that MEM is declared as a WORD.	

CBW	Convert BYTE to WORD	0 D I T S Z A P C 
Description:		
This instruction sig	gn extends the byte in AL into AX	
Example	Function	
CBW	Sign extend AL into AX	

CDQ	Convert DWORD to QWORD (80386 or later)	0 D I T S Z A P C 
Description:		
This instruction sign	extends the 32 bit value in EAX into EDX.	
Example	Function	
CDQ	Sign extend EAX into EDX	

CLC	Clear carry flag	0 D I T S Z A P C 0
Description:		
This instruction will set the carry flag to 0.		
Example	Function	
CLC	Set carry flag to 0	

CLD	Clear direction flag	0 D I T S Z A P C - 0
<b>Description</b> : This instruction will set the direction flag to 0. This will cause string instructions to increment the pointer registers.		
Example	Function	
CLD	Set direction flag to 0 (string instructi	ons increment index registers)

CLI	Clear interrupt flag	0 D I T S Z A P C 0
<b>Description</b> : This instruction will set the interrupt enable flag to 0. This causes interrupts to be disabled.		
Example Function		
CLI	Interrupt flag set to 0 (interrupts disa	abled)

CLTS	Clear the task-switched flag (80286 or later)	0 D I T S Z A P C 
<b>Description</b> : This instruction sets the task switched bit (TS) in the MSW (80286) or CR0 register (80386 or later) to 0.		
Example	Function	
CLTS	Task-switched flag in MSW or CR0 set to	0 0

CMC	Complement carry	0 D I T S Z A P C *	
Description:	Description:		
This instruction complements the state of the carry flag in the flags register. If the flag is 1, it will be set to 0. If the flag is 0, it will be set to 1			
Example	Function		
CMC	Complements (inverts) the carry flag	g	

СМР	Compare operands         O D I T S Z A P C           * * * * * *
Description:	
This instruction compares t	he two operands. The contents of the source operand is subtracted
	stination operand and the flags are set to correspond to the result of
the subtraction. The result	of the subtraction is not stored.
General Forms	Function
CMP reg,idata	Subtract idata from reg and set the flags accordingly
CMP mem,idata	Subtract idata from the contents of mem and set the flags
	accordingly
CMP regd, regs	Subtract regs from regd and set the flags accordingly
CMP reg,mem	Subtract the contents of <i>mem</i> from <i>reg</i> and set the flags accordingly
CMP mem,reg	Subtract reg from the contents of mem and set the flags accordingly
Examples	
CMP BL,CL	Compare BL with CL
CMP MEM,AX	Compare word at memory location DS:MEM with AX
CMP ECX,DAY1	Compare ECX with the DWORD at memory location DS:DAY1
CMP AL,2	Compare AL with the constant 2
CMP DATA2,1	Compare the contents of memory location DS:DATA2 with 1

CMPS	Compare strings	0 D I T S Z A P C * * * * * *
<b>Description</b> : This instruction subtracts the memory location specified by DS:SI (or DS:ESI) from the operand specified by ES:DI (or ES:EDI), setting the flags and discarding the result, was with the CMP instruction. The size of the operand can be either a BYTE, WORD, or DWORD. Following the comparison, SI (ESI) and DI (EDI) will be either incremented or decremented, depending on the state of the direction flag, by an amount appropriate to the size of the operands.		
Example	Function	
CMPSB CMPSW CMPSD	Compare memory byte at DS:SI with r Compare memory word at DS:SI with Compare memory dword at DS:SI with	memory word at ES:DI

CMPXCHG		D I T S Z A P C * * * * *
Description:		
Example	Function	
CMPXCHG CX,BX CMPXCHG MEM,DX	Compare CX with AX, if equal CX<=BX else AX<=E Compare DS:MEM with AX, if equal MEM<=DX else	

CMPXCHG8B	Compare and exchange 8 bytes (80486 and later)	0 D I T S Z A P C *
Description:		
Example	Function	
CMPXCHG8B MEM	Compare DS:MEM with EDX:EAX, if equal M MEM<=EDX:EAX	EM<=ECX:EBX else

CPUID	Get CPU identification (Pentium or later)	0 D I T S Z A P C *
Description:		
Example	Function	
CPUID	EAX <= CPU identification information	

CWD	Convert WORD to DWORD	0 D I T S Z A P C 
Description: This instruction sign extends the word in AX into DX:AX		
Example	Function	
CWD	Sign extend AX into DX:AX	

CWDE	Convert WORD to DWORD (80386 or later)	0 D I T S Z A P C 
Description:		
This instruction will sign extend the word in AX into EAX.		
Example	Function	
CWDE	Sign extend AX into EAX	

DAA	Decimal adjust after addition	0 D I T S Z A P C ? * * * * *
<b>Description</b> : This instruction is used following an addition on packed decimal data to ensure that the value in AL contains a correct decimal result.		
Example	Function	
DAA	Adjust the contents of AL after BCD additio	n

DAS	Decimal adjust after subtraction	0 D I T S Z A P C ? * * * * *
<b>Description</b> : This instruction is used following a subtraction of packed decimal data to ensure that the value in AL contains a correct decimal result.		
Example	Function	
DAS	Adjust the contents of AL after BCD subtracti	on

DEC	Decrement	0 D I T S Z A P C * * * * * -
Description:		
This instruction subtracts 1	from the specified operand. This instruction do	es not affect the carry
flag, but affects all other co	ondition code flags.	
General Forms	Function	
DEC reg	Subtract 1 from reg	
DEC mem	Subtract 1 from mem	
Example		
DEC BH	Subtract 1 from BH	
DEC CX	Subtract 1 from CX	
DEC MEM[BX]	Subtract 1 from the contents of memory locat	tion DS:MEM+BX
DEC EDX	Subtract 1 from EDX	

DIV	Divide (unsigned)	0 D I T S Z A P C ? ? ? ? ? ?
Description:		
This instruction performs an unsigned division of the value in the accumulator register or register pair by the specified operand, storing the quotient in the low part of the accumulator and the remainder in the high part of the accumulator. For BYTE operands, the accumulator is AX, with the resulting quotient in AL and the remainder in AH. For WORD operands, the accumulator is DX:AX, with the resulting quotient in AX and the remainder in DX. For DWORD operands, the accumulator is EDX:EAX, with the resulting quotient in EAX and the remainder in EDX.		
General Forms	Function	
DIV BH	Divide AX by BH, AH<=remainder, AL<=quoti	
DIV CX	Divide DX:AX by CX; DX<=remainder, AX<=q	uotient
DIV ESI	Divide EDX:EAX by ESI; EDX<=remainder, EA	AX<=quotient
Example		
DIV BH	Divide AX by BH, AH<=remainder, AL<=quoti	ent
DIV CX	Divide DX:AX by CX; DX<=remainder, AX<=q	uotient
DIV ESI	Divide EDX:EAX by ESI; EDX<=remainder, E	AX<=quotient

ENTER	Create a stack frame (80186 or later)	0 D I T S Z A P C 
Description:		
When the second operand onto the stack to allow add the current procedure. The PUSH BP MOV BP,SP SUB SP, <i>n</i>	a stack frame reserving space for local va is greater than 0, the pointers to previous dressing of stack resident variables whose s ENTER <i>n</i> ,0 instruction is equivalent to this	stack frames are pushed scopes contain the scope of
Examples	Function	
ENTER 16,0	Create a stack frame of 16 bytes for leve	el O
ENTER 32,1	Create a stack frame of 32 bytes for leve	el 1

HLT	Halt		0 D I 1 	Г S Z A P C
Description:		 		

This instruction stops the processor. No other instructions will execute until the processor is brought out of the halt state by a reset or an interrupt. An NMI or reset will always bring the processor out of the halt state. If the halt state is entered with maskable interrupts disabled (IF = 0), then these interrupts will not be acknowledged or bring the processor out of the halt state. Execution will resume at the instruction following the HLT instruction after the interrupt service routine is completed.

Example	Function
HLT	Halts all processing until a reset or interrupt occurs

IDIV	Divide (signed)	0 D I T S Z A P C ? ? ? ? ? ?
Description:		

This instruction performs a signed division of the value in the accumulator register or register pair by the specified operand, storing the quotient in the low part of the accumulator and the remainder in the high part of the accumulator. For BYTE operands, the accumulator is AX, with the resulting quotient in AL and the remainder in AH. For WORD operands, the accumulator is DX:AX, with the resulting quotient in AX and the remainder in DX. For DWORD operands, the accumulator is EDX:EAX, with the resulting quotient in EAX and the remainder in EDX.

General Forms	Function
IDIV BH	Divide AX by BH, AH<=remainder, AL<=quotient
IDIV CX	Divide DX:AX by CX; DX<=remainder, AX<=quotient
IDIV ESI	Divide EDX:EAX by ESI; EDX<=remainder, EAX<=quotient
Example	
IDIV BH	Divide AX by BH; AH<=remainder, AL<=quotient
IDIV CX	Divide DX:AX by CX; DX<=remainder, AX<=quotient
IDIV ESI	Divide EDX:EAX by ESI; EDX<=remainder, EAX<=quotient

IMUL	Multiply (signed)ODITSZAPC* ? ? ? ? *			
Description:	Description:			
This instruction performs a	signed multiply. The flags are left in an indeterminate state except for			
	red to 0 if the result of the multiplication is the same size as the			
multiplicand.				
In the single operand form	of the instruction, the result is placed in AX if the operands are BYTE,			
	s, and EDX:EAX for DWORD operands. The multiple operand forms of			
the instruction only exist on	80386 and later processors.			
General Forms	Function			
IMUL reg	acc <- acc * reg			
IMUL mem	acc <- acc * mem			
IMUL regd, regs	regd <- regd * regs			
IMUL regd, mem	regd <- regd * mem			
IMUL regd,idata	regd <- regd * idata			
IMUL regd, regs, idata	regd <- regs * idata			
IMUL regd, mem, idata	regd <- mem * idata			
Example				
IMUL CL	Multiply CL times AL; product replaces AX			
IMUL CX	Multiply CX times AX; product replaces DX:AX			
IMUL ECX	Multiply ECX times EAX; product replaces EDX:EAX			
IMUL DX,AX,2	Multiply AX times 2; product replaces DX			
IMUL MEM	Multiply AX times contents of memory location DS:MEM; product			
	replaces DX:AX			

IN	Read data from input port	0 D I T S Z A P C	
Description:			
This instruction reads a	a BYTE, WORD or DWORD into the accumulato	r from an I/O port. The	
immediate form of the i	nstruction only allows a BYTE sized operand, ar	nd thus restricts access to	
the first 256 I/O ports. I	the first 256 I/O ports. Placing the 16 bit port address in DX allows access to all I/O ports. The		
accumulator is either A	accumulator is either AL, AX or EAX.		
General Forms	Function		
IN acc,idata			
IN acc,DX			
Example			
IN AL,20H	Input data from port 20H to AL		
IN AX,DX	Input data from port in DX to AX		

INC	Increment	0 D I T S Z A P C * * * * * -
Description:		
This instruction will add 1 to	o the value in the specified operand. This instruct	ion does not affect
the carry flag, but affects a	Il other condition code flags.	
General Forms	Function	
INC reg	Add 1 to reg	
INC mem	Add 1 to mem	
Example	•	
INC DH	Add 1 to DH	
INC MEM	Add 1 to contents of memory location DS:MEM	
INC EDX	Add 1 to EDX	

INS	Input string (80186 or later)	0 D I T S Z A P C 
Description:		
This instruction will read a value from the input port specified by DX and place the result in the memory location specified by ES:DI (or ES:EDI). The DI (or EDI) register will then be incremented or decremented, depending on the state of the direction flag, by an amount appropriate to the size of the operand. (1 for BYTE, 2 for WORD, 4 for DWORD).		
Example	Function	
INSB	Input byte sized data from port DX in	
INSW	Input word sized data from port DX ir	nto memory at ES:DI
INSD	Input dword sized data from port DX	

INT	Software interrupt	0 D I T S Z A P C 
Description:		
	current flags and execution location on the stac specified by the interrupt vector.	k. Control is then
General Form	Function	
INT vector	Software interrupt using vector.	
Example		
INT 3	Software interrupt using vector 3. This is a sp instruction used for debugger breakpoint	
INT 21H	Software interrupt using vector 21H, Two byte	e instruction

INTO	Interrupt on overflow	0 D I T S Z A P C 
<b>Description</b> : This instruction will test the state of the overflow flag and signal an exception if it is set by executing an INT 4.		
Example	Function	
INTO	Interrupt using vector 4 if overflow fla	g = 1

INVD	Invalidate cache (80486 or later)	0 D I T S Z A P C 
Description:		
Example	Function	
INVD	Data in the internal cache is invalidated or	rerased

INVLPG	Invalidate TLB (80486 or later)	0 D I T S Z A P C 
Description:		
Example	Function	
INVLPG	Clears translation look-aside buffer	

IRET/IRETD	Return from interrupt	O D I T S Z A P C ? ? ? ? ? ? ? ? ? ?	
Description:			
This instruction is used to perform a return from an interrupt service routine. This instruction will pop the IP, CS, and Flags from the stack to return control to the location interrupted by either a hardware interrupt of a software interrupt.			
Example	Function		
IRET	16 bit FAR return from interrupt, pops FLAGS, CS, IP		
IRETD	32 bit FAR return from interrupt, pops EFLAGS, CS, EIP		

Jcc	Conditional jump		
Description:	Description:		
The Jcc instructions test the conditions described for each mnemonic. If the condition is met, the			
processor branches to the specified location within the current code segment. If the condition is			
false, execution continue	s with the instruction following the jump. On the 80286 and earlier		
processors, the target of	the branch is specified with an 8 bit IP relative displacement. This limits		
	or the jump to +/- 127 bytes approximately. On the 80386 and later		
	acement is allowed, allowing the target of the jump to be anywhere		
within the current segme	nt.		
General Form	Function		
Jcc offset	Jump if condition is true		
Examples			
JA LOC	Jump to LOC if above (unsigned x>y) (CF=0 & ZF=0)		
JAE LOC	Jump to LOC if above or equal (CF=0)		
JB LOC	Jump to LOC if below (unsigned x <y) (cf="1)&lt;/td"></y)>		
JBE LOC	Jump to LOC if below or equal (CF=1   ZF=1)		
JC LOC	Jump to LOC if carry (CF=1)		
JCXZ LOC	Jump to LOC if CX=0		
JECXZ LOC	Jump to LOC if ECX=0		
JE LOC	Jump to LOC if equal (ZF=1)		
JG LOC	Jump to LOC if greater (signed x>y) (CF=0F & ZF=0)		
JGE LOC	Jump to LOC if greater or equal (SF=OF)		
JL LOC	Jump to LOC if less (signed x <y) &="" (sf!="OF" zf="0)&lt;/td"></y)>		
JLE LOC	Jump to LOC if less or equal (SF!=OF)		
JNA LOC	Jump to LOC if not above (same as JBE)		
JNAE LOC	Jump to LOC if not above or equal (same as JB)		
JNB LOC	Jump to LOC if not below (same as JAE)		
JNBE LOC	Jump to LOC if not below or equal (same as JA)		
	Jump to LOC if carry not set $(CF=0)$		
JNE LOC JNG LOC	Jump to LOC if not equal (ZF=0) Jump to LOC if not greater (SF!=OF & ZF=1)		
JNGE LOC	Jump to LOC if not greater or equal (same as JL)		
JNGE LOC	Jump to LOC if not less than (same as JGE)		
JNLE LOC	Jump to LOC if not less than or equal (same as JG)		
JNO LOC	Jump to LOC if not overflow (OF=0)		
JNP LOC	Jump to LOC if no parity (PF=0) (odd parity)		
JNS LOC	Jump to LOC no sign (SF=0) (positive number)		
JNZ LOC	Jump to LOC if not zero (ZF=0)		
JO LOC	Jump to LOC if overflow (OF=1)		
JP LOC	Jump to LOC if parity (PF=1) (even parity)		
JPE LOC	Jump to LOC if parity even (PF=1)		
JPO LOC	Jump to LOC if parity odd (PF=0)		
JS LOC	Jump to LOC if sign (SF=1) (negative number)		
JZ LOC	Jump to LOC if zero (ZF=1)		

JMP	Near Jump		
Description:			
This instruction transfers execution of the program to a new location. A new value is loaded into IP (or EIP) to perform the transfer of control. For the JMP <i>offset</i> form of the instruction, the target address is specified as a signed displacement that is added to the current contents of IP (or EIP). For the other forms of the instruction, the operand value replaces the current value of IP (or EIP).			
General Forms	Function		
JMP offset	Add offset to the current value in IP		
JMP reg	Replace the contents of IP with the contents of reg		
JMP mem	Replace the contents of IP with the contents of mem		
Example			
JMP LOC	Jump to LOC.		
JMP DX	Jump to address in DX		
JMP NEAR PTR MEM	Jump NEAR to the address whose offset is in the WORD at memory location DS:MEM		
JMP FAR PTR MEM	Jump FAR to the address contained in the DWORD at DS:MEM		

JMP	Far Jump	0 D I T S Z A P C	
Description:			
This instruction transfers execution of the program to a new location. The contents of the specified operand are loaded into IP (or EIP) and CS.			
General Forms	Function		
JMP idata	Replace CS:IP with <i>idata</i> .		
JMP mem	Replace CS:IP with the contents of mem.		
Example	·		
JMP LOC	Jump far to LOC.		
JMP TABLE[SI]	Load CS:IP from the contents at the indicated n	nemory location.	
JMP FAR PTR MEM	Jump FAR to the address contained in the DWC		

LAHF	Load AH from the FLAGS	0 D I T S Z A P C 
Description:		
This instruction moves the contents of the low byte of the FLAGS register into AH.		
Example	Function	
LAHF	The low byte of the flags register is copied	to AH

LAR	Load access rights (80286 or later)	0 D I T S Z A P C *
Description:		
Example	Function	
LAR AX,BX	The access rights are loaded to AX from BX	

LDS/LES/LFS/	0 D I T S Z A P C	
LGS/LSS	Load far pointer	
<b>Description</b> : This instruction will load a far pointer into a segment register plus the other specified register. The specified memory location contains the offset which will be loaded into a general purpose register, and the following location contains a segment value which will be loaded into the specified segment register.		
General Forms	Function	
Lseg reg,mem	Load <i>reg</i> with the value at <i>mem</i> and load segment register <i>seg</i> with the contents of <i>mem</i> +2 (or <i>mem</i> +4 for 32 bit operations)	
Example		
LDS DI,MEM	Load DS and DI from the DWORD at DS:MEM	
LES AX,MEM	Load ES and AX from the DWORD at DS:MEM	
LDS ESI,MEM	Load DS and ESI from the FWORD at DS:MEM	
LES BX,ES:MEM	Load ES and BX from the DWORD at ES:MEM	
LSS SP,MEM	Load SS and SP from the DWORD at DS:MEM	

LEA	Load effective address				
Description:	Description:				
This instruction loads the	address specified by the memory operand into	the specified register.			
The effective address cald	culation specified by the addressing mode of the	he memory operand is			
performed, and the resulti	ng address (offset) is loaded into the register.				
General Form	Function				
LEA reg,mem	n Load the <i>reg</i> with the effective address of <i>mem</i> .				
Example					
LEA BX,MEM Load the offset of MEM to BX					
LEA DX,MEM[SI][BX]	Load DX with the offset of MEM+SI+BX				
LEA SI,[DI+4]	Load SI with the offset of DI+4				

LEAVE		Leave procedure (80186 or later)	0 D I T S Z A P C 
Description: This instruction is the inverse of the ENTER instruction. LEAVE is used immediately before return from a procedure call to remove the stack frame created by ENTER. This instruction is the equivalent of the following instructions: MOV SP,BP POP BP			
Example		Function	
LEAVE		Reverses the action of EN	ER

LGDT	Load global descriptor table register (80286 or later)	0 D I T S Z A P C 
Description:		
Example	Function	
LGDT MEM64	Loads the global descriptor table register from the 8 byte structure at memory location DS:MEM64	

LIDT	Load interrupt descriptor table register (80286 or later)	0 D I T S Z A P C 
Description:		
Example	Function	
LIDT MEM64	Loads the interrupt descriptor table register from the 8 byte structure at memory location DS:MEM64	

LLDT	Load local descriptor table register (80286 or later)	0 D I T S Z A P C 
Description:		
Example	Function	
LLDT AX LLDT MEM[SI]	Loads the local descriptor table register with the Loads the local descriptor table register with the memory at location DS:MEM+SI	selector in AX selector stored in

LMSW	Load machine status word (80286 or later)	0 D I T S Z A P C 
	es the contents of the machine status word into the processor, it will move the contents of the low 16	
Example	Function	
LMSW AX	Copies the contents of AX into the machin instruction should only be used on an 802 been superceded by the MOV CR0,EAX in later processors.	86 processor, as it has

LODS	Load string	0 D I T S Z A P C 
accumulator. Follo	I load the BYTE, WORD, or DWORD at I wing the load, SI (or ESI) will be increme ection flag, by an amount appropriate to t	nted or decremented, depending on
Example	Function	
LODSB LODSW LODSD	Load AL from the BYTE at mer Load AX from the WORD at m Load EAX from the DWORD a	emory location DS:SI

LOOPcc	Loop control. Decrement CX and
Description:	
	a decrement and branch operation. The CX (or ECX) register is esult is 0, the branch is not taken. If the result of the decrement is not 0,
	or all variants other than LOOP, in addition to the decrement of CX, a performed to determine if the branch should be taken.
General Forms	Function
LOOPcc off	
Example	
LOOP LOC	Decrement CX, if CX not zero, jump to location CS:LOC
LOOPD LOC	Decrement ECX, if ECX not zero, jump to location CS:LOC
LOOPZ LOC	Decrement CX, if CX not zero and ZF=1, jump to location CS:LOC
LOOPNZ LOC	Decrement CX, if CX not zero and ZF=0, jump to location CS:LOC
LOOPE LOC	Same as LOOPZ
LOOPNE LOC	Same as LOOPNZ

LSL	Load segment limit (80286 or later)	0 D I T S Z A P C *
Description:		
Example	Function	
LSL AX,BX	Load AX with the segment limit from the sele	ector in BX

LTR	Load task register (80286 or later)	0 D I T S Z A P C 
Description:		
Example	Function	
LTR AX	Loads the selector in AX into the task register	er

MOV	Move data		
Description:			
This instruction copies the	contents of the source operand into the destination operand.		
General Forms	Function		
MOV reg,idata	Move immediate value <i>idata</i> into register reg		
MOV mem,idata	Move immediate value <i>idata</i> into memory location mem		
MOV regd, regs	Move the contents of regs into regd		
MOV reg,mem	Move the contents of memory location mem into reg		
MOV mem, reg	Move the contents of reg into memory location mem		
Examples			
MOV CX,BX	Move the contents of BX to CX		
MOV MEM,AL	Move the contents of AL to the byte at memory location DS:MEM		
MOV ECX,MEM	Move the contents of the DWORD at DS:MEM to ECX		
MOV MEM,3	Move the immediate value 3 to the memory location at DS:MEM		
MOV DX,MEM[SI+4]	Move the contents of memory location DS:MEM+SI+4 to DX		

MOV	Move selector/segment				
Description:					
This instruction copies the	This instruction copies the contents of the source operand into the destination segment register.				
General Forms	Function				
MOV sreg, reg	Move the contents of reg into segment register sreg				
MOV sreg,mem	Move the contents of memory location mem into segment register				
MOV reg,sreg MOV mem,sreg	sreg Move the contents of segment register sreg into register reg Move the contents of segment register sreg into memory location mem				
Examples					
MOV DS,AX	Move the contents of AX into DS				
MOV ES,ES:[BX+2]	Move the contents of the WORD at memory location ES:BX+2 to ES				
MOV DX,SS	Move the contents of SS into DX				
MOV MEM,DS	Move the contents of DS into memory location DS:MEM				

Move special (80386 or later)	-				· _	A -	P (	-
Function								
Move the contents of EAX to Control Register 0								
Move the contents of DR1 to EAX								
	(80386 or later) Function Move the contents of EAX to Control Register 0	(80386 or later)	(80386 or later) Function Move the contents of EAX to Control Register 0	(80386 or later) Function Move the contents of EAX to Control Register 0	(80386 or later) Function Move the contents of EAX to Control Register 0	(80386 or later)	(80386 or later)	(80386 or later) Function Move the contents of EAX to Control Register 0

MOVS	Move string	0 D I T S Z A P C 		
Description:				
location specified by ES:D will be incremented or dec	This instruction copies the memory operand specified by DS:SI (or DS:ESI) to the memory location specified by ES:DI (or ES:EDI). Following the memory copy, SI and DI (or ESI and EDI) will be incremented or decremented, depending on the state of the direction flag, by an amount corresponding to the size of the operand transferred.			
Example	Function			
MOVSB	Move the byte at memory location DS:SI to memory location ES:DI			
MOVSW	Move the word at memory location DS:SI to memory location ES:DI			
MOVSD	Move the dword at memory location DS:ESI	to location ES:EDI		

MOVSX	Move and sign extend (80386 or later)	0 D I T S Z A P C	
Description:			
This instruction is used to convert a signed 8 bit value into a signed 16 bit value, or a signed 16 bit value into a signed 32 bit value. The sign bit of the source operand will be replicated through the high byte (for 8 -> 16 extension) or word (for 16 -> 32 bit extension) of the destination			
Example	Function		
MOVSX AX,AL	Sign extend AL into AX		
MOVSX EDX,DX	Sign extend DX into EDX		
MOVSZ ECX,MEM	Sign extend the word at memory locatio	n DS:MEM into ECX	

MOVZX	Move and zero extend (80386 or later)	0 D I T S Z A P C 
Description:		
unsigned 16 bit value in	to convert an unsigned 8 bit value into an uns to an unsigned 32 bit value. The high byte (fo stension) will be filled with 0.	
Example	Function	
MOVZX AX,AL	Zero extend AL into AX	
MOVZX EBX,AX	Zero extend AX into EBX	
MOVZX EDX,MEM	Zero extend the word at memory locatio	n DS:MEM into EDX
MUI	Insigned multiplication	ODITSZAPC

MUL	Unsigned multiplication ODITSZAPC
Description:	
This instruction performs a	an unsigned multiply. The flags are left in an indeterminate state except
for OF and CF, which are	cleared to 0 if the result of the multiplication is the same size as the
multiplicand.	
In the single operand form	of the instruction, the result is placed in AX if the operands are BYTE,
DX:AX for WORD operand	ds, and EDX:EAX for DWORD operands. The multiple operand forms of
the instruction only exist o	n 80386 and later processors
General Forms	Function
MUL reg	acc <- acc * reg
MUL mem	acc <- acc * mem
MUL regd, regs	regd <- regd * regs
MUL regd,mem	regd <- regd * mem
MUL <i>regd</i> ,idata	regd <- regd * idata
MUL regd, regs, idata	regd <- regs * idata
MUL regd, mem, idata	regd <- mem * idata
Example	
MUL CL	Multiply CL times AL, the product replaces AX
MUL CX	Multiply CX times AX, the product replaces DX:AX

NEG	Negate	0 D I T S Z A P C * * * * * *
Description:		
This instruction subtracts operand.	its operand from 0. This results in the 2's compl	ement negation of the
General Form	Function	
NEG reg	Negate the contents or reg	
NEG mem	Negate the contents of mem.	
Example		
NEG CX	Negate the contents of CX	
NEG ARRAY[SI+2]	Negate the contents of the specified memory	/ location

NOP	No operation	O D I T S Z A P C
Description:		
This instruction pe	erforms no operation.	
Example		
NOP	No operation	

NOT	Complement or logical negation
Description: This instruction perfor is inverted.	ms the logical, bitwise complement of its operand. Each bit of the operand
General Form	Function
NOT reg	Invert the bits of <i>reg</i>
NOT mem	Invert the bits of the memory location mem
Example	
NOT AX	Invert the bits of AX
NOT VAR	Invert the bits of memory location VAR
NOT ARRAY[DI]	Invert the bits of memory location ARRAY+DI

OR	Logical inclusive OR		
Description:			
This instruction performs a	logical OR operation between each bit of the source operand and		
each bit of the destination of	operand. The result is stored in the destination.		
General Form	Function		
OR reg,idata	Logical OR reg with idata		
OR mem,idata	Logical OR contents of memory location mem with idata		
OR regd, regs	Logical OR regd with regs		
OR reg,mem	Logical OR reg with contents of memory location mem		
OR mem,reg	Logical OR contents of memory location mem with reg		
Examples			
OR AL,07FH	Sets all but the high bit of AL		
OR DATA3,DX	Logical OR of word at memory location DS:DATA3 with DX		
OR CL,ES:[DI+2]	Logical OR of byte at memory location ES:DI+2 with CL		
OR BX,CX	Logical OR of BX with CX		
OR AX,MASK[SI]	Logical OR of word at memory location DS:MASK+SI with AX		

OUT	Write data to output port	0 D I T S Z A P C 
Description:		
This instruction writes the	alue in the accumulator (AL or AX) to the specif	ied data port. Using an
immediate value as the pol	rt address allows access to ports 0-255 (0-0FFh	). In order to access
any output port address (0-	FFFF) it is necessary to use the out dx,ax form	of the instruction
General Form	Function	
OUT idata,acc		
OUT DX, <i>acc</i>		
Examples	·	
OUT 27h,AL	Write the value in AL to port 27h	
OUT DX,AX	Write the value in AX to port at address in DX	

OUTS	Output string (80186 or later)	0 D I T S Z A P C 
Description:	- the last of a second second second sections	
This instruction will write the byte, word, or dword at location DS:SI (DS:ESI for 32 bit operation) to the output port whose address is in DX. (EDX for 32 bit operation). The SI (ESI) register will then be adjusted according to the size of the operand and the setting of the direction flag. The OUTS instruction can be prefixed with a REP prefix, in which case, CX (ECX) contains the number of times the OUTS instruction is to be repeated.		
General Form	Function	
OUTSB	Output byte to port	
OUTSW	Output word to port	
OUTSD	Output dword to port	
Example	· · · · ·	
OUTSB	Write byte at DS:SI to output	t port whose address is in DX

POP	Pop data from stack	0 D I T S Z A P C 
Description:		
This instruction pops the adjusts the stack pointer.	current value from the top of the stack, stores it in	the destination, and
General Form	Function	
POP reg	POP top of stack into reg	
POP mem	POP top of stack into memory location mem	
Example		
POP CX	POP top of stack into CX	
POP VAR1	POP top of stack into memory location VAR1	

POP	Pop segment register from stack	0 D I T S Z A P C
	pop the current value from the top of the stack into the stack pointer. The CS register is not a valid destin ay be used.	
General Form	Function	
POP sreg	POP top of stack into segment register sreg	
Example		
POP DS	POP the top of the stack into DS	

POPA/POPAD	Pop all general registers (80186 or later)	0 D I T S Z A P C 
Description:		

This instruction will pop all general purpose registers (16 bit for POPA, 32 bit for POPAD) from the top of the stack and adjust the stack pointer.

The registers are popped in the following order: DI, SI, BP, SP, BX, DX, CX, AX

This instruction was introduced with the 80186, and does not exist in earlier processors.

Function	
POP 16 bit general registers from stack	
POP 32 bit general registers from stack	
	POP 16 bit general registers from stack

POPF/POPFD	Pop flags from stack			5 Z ? ?		
<b>Description</b> : This instruction pops the FLAGS register (EFLAGS for POPFD) from the top of the stack and adjusts the stack pointer.						
General Form	Function					
POPF	POP flags from top of stack to FLAGS register					
POPFD	POP flags from top of stack to EFLAGS registe	r				
Example	· · · · · · · · · · · · · · · · · · ·					
POPF			 			

PUSH	Push data onto stack	
Description:		
This instruction pushes the	operand onto the stack, and adjusts the stack pointer. The operand	
pushed becomes the new	op of the stack.	
General Form	Function	
PUSH idata	PUSH immediate value onto the stack	
PUSH reg	PUSH contents of <i>reg</i> onto the stack	
PUSH mem	PUSH contents of memory location mem onto the stack	
Example		
PUSH 12	PUSH the value 12 onto the stack	
PUSH DX	PUSH the contents of register DX onto the stack	
PUSH TABLE[BX+2]	PUSH the contents of the memory location onto the stack	

PUSH	Push segment register onto stack	0 D I T S Z A P C 	
Description:	Description:		
This instruction will	This instruction will push the contents of the specified segment register onto the stack and adjust		
the stack pointer. The	the stack pointer. The operand pushed becomes the new top of the stack.		
General Form	General Form Function		
PUSH sreg PUSH sreg onto the stack			
Example			
PUSH ES	PUSH the contents of ES onto the stack		

PUSHA/		ODITSZAPC
PUSHAD	Push all general registers onto stack (80186 or later)	
Description:		
	e contents of all of the general purpose registers	s (16 bit for PUSHA,
32 bit for PUSHAD) onto th	e stack and adjust the stack pointer.	
General Form	Function	
PUSHA	PUSH 16 bit general registers onto the stack	
PUSHAD	PUSH 32 bit general registers onto the stack	
Example		
PUSHA		

PUSHF/	0 D I T S Z A P C
PUSHFD	Push flags onto stack
<b>Description</b> : This instruction pushes the adjusts the stack pointer.	FLAGS register (EFLAGS for PUSHFD) onto the top of the stack and
General Form	Function
PUSHF PUSHFD	PUSH 16 bit flags onto the stack PUSH 32 bit eflags onto the stack
Example	· · ·
PUSHF	

RCL	Rotate left through carry	0 D I T S Z A P C * *
Description:		
This instruction concatenat	es the carry flag with the specified operand and	rotates the result left
by the specified number of	bit positions. For each bit position of rotation, t	he current contents of
the carry flag goes to the lo	w bit position of the operand, and the high bit o	of the operand goes to
	ocessors prior to the 80386, the only valid value	
General Form	Function	
RCL reg,idata	Rotate register reg left through carry by idata	bit positions
RCL mem,idata	Rotate memory location mem left by idata bit	positions
RCL reg,CL	Rotate register reg left by the number of bit p	ositions in CL
RCL mem,CL	Rotate memory location mem left by the num	ber of bit posn's in CL
Example		
RCL BX,1	Rotate register BX left through carry by 1 bit p	position
RCL VAR,CL	Rotate memory location VAR left through car	ry by CL bit positions
RCL DL,CL	Rotate register DL left through carry by CL bit	t positions

RCR	Rotate right through carry	0 D I T S Z A P C * *	
Description:			
	es the carry flag with the specified operand an		
	bit positions. For each bit position of rotation,		
	w bit position of the operand, and the high bit		
	ocessors prior to the 80386, the only valid valu	ie for <i>idata</i> is 1)	
General Form	General Form Function		
RCR reg,idata	Rotate register reg right through carry by ida		
RCR mem,idata	Rotate memory location mem right by idata bit positions		
RCR reg,CL	Rotate register reg right by the number of bit positions in CL		
RCR mem,CL Rotate memory location mem right by the number of bit posn's in		mber of bit posn's in CL	
Example			
RCR BX,1	Rotate register BX right through carry by 1 b	it position	
RCR VAR,CL	Rotate memory location VAR right through c	arry by CL bit positions	
RCR DL,CL	Rotate register DL right through carry by CL		

REPcc	Repeat string prefix   ODITSZAPC	
Description:		
The repeat prefix may be a	applied to any string instruction. When used with a string instruction,	
	ster (ECX for 32 bit operation) will be decremented and the string	
	X goes to 0. If a REPcc form of the prefix is used, then the state of ZF	
is also tested when using C	CMPS or SCAS instructions.	
General Form	Function	
REP	Repeat while CX (ECX) is not 0	
REPE	Repeat while CX (ECS) is not 0 and ZF is set	
REPZ	Repeat while CX (ECX) is not 0 and ZF is set. (same as REPE)	
REPNE	Repeat while CX (ECX) is not 0 and ZF is clear	
REPNZ	Repeat while CX (ECX) is not 0 and ZF is clear (same as REPNE)	
Example		
REP MOVSB	Repeat MOVSB while CX is not 0	
REPZ SCASW	Repeat SCSAW while CX is not 0 and ZF is set	
REPNE CMPSB	Repeat CMPSB while CX is not 0 and ZF is clear	

RET	Near return from procedure	0 D I T S Z A P C 
Description:		
This instruction restores the IP register (EIP for 32 bit operation) to the value it held before the last CALL instruction. The previous value of IP (EIP) is popped from the stack. If the optional <i>idata</i> operand is present, the <i>idata</i> value is added to SP (ESP) after the return address is popped		
from the stack.		
General Form	Function	
RET	Return from near subroutine call	
RET idata	Return from near subroutine call and adjust	st stack by <i>idata</i>
Example		
RET	Return from subroutine	
RET 4	Return from subroutine and then add 4 to	SP (ESP)

RETF	Far return from procedure   ODITSZAPC	
Description:		
This instruction restore	es the CS and IP registers (CS and EIP for 32 bit operation) to the values	
	ALL instruction. The previous values of IP (EIP) and CS are popped from	
the stack. If the option	al idata operand is present, the idata value is added to SP (ESP) after the	
return address is popp	bed from the stack.	
General Form	Function	
RETF	Return from far subroutine call	
RETF idata	Return from far subroutine call and adjust stack by idata	
Example		
RETF	Return from subroutine call	
RETF 8	Return from subroutine call and add 8 to SP (ESP)	

ROL	Rotate left	0 D I T S Z A P C * *
Description:		
	destination operand left by the specified nu	
	, the high bit position of the destination goes	
also to the carry flag. (Note	e: on processors prior to the 80386, the only	valid value for <i>idata</i> is 1)
General Form	Function	
ROL reg,idata	Rotate register reg left by idata bit position	
ROL mem,idata	Rotate memory location mem left by idata	
ROL reg,CL	Rotate register reg left by the number of bit positions in CL	
ROL mem,CL Rotate memory location mem left by the number of bit posn's in		number of bit posn's in CL
Example		
ROL BX,1	Rotate register BX left by 1 bit position	
ROL VAR,CL	Rotate memory location VAR left by CL bi	it positions
ROL DL,CL	Rotate register DL left by CL bit positions	

ROR	Rotate right ODITSZAP	
Description:		
This instruction rotates the destination operand right by the specified number of bit positions. For each bit position of rotation, the low bit position of the destination operand goes to the high bit position and also to the carry flag. (Note: on processors prior to the 80386, the only valid value for <i>idata</i> is 1)		
General Form Function		
ROR reg,idata	Rotate register reg right by idata bit positions	
ROR mem,idata	Rotate memory location <i>mem</i> right by <i>idata</i> bit positions	
ROR reg,CL	Rotate register reg right by the number of bit positions in CL	
ROR mem,CL	Rotate memory location mem right by the number of bit posn's in CL	
Example		
ROR BX,1	Rotate register BX right by 1 bit position	
ROR VAR,CL	Rotate memory location VAR right by CL bit positions	
ROR DL,CL	Rotate register DL right by CL bit position	S

SAHF	Store AH to flags	0 D I T S Z A P C * * * * *	
Description:			
This instruction tran	nsfers the contents of the AH register to the le	ow 8 bit positions of the FLAGS	
register (EFLAGS f	register (EFLAGS for 32 bit operation).		
General Form	Function		
SAHF	Set flags from AH		
Example	Example		
SAHF	Set flags from AH		

SAL	Shift left arithmetic	0 D I T S Z A P C * * * ? * *	
Description:			
This instruction shifts the d	estination operand left arithmetically by the sp	ecified number of bit	
positions. The low order bit	positions of the destination are set to 0. The h	high order bits shifted	
	st. The arithmetic shift left (SAL) and logical s		
equivalent operations. (Not	e: on processors prior to the 80386, the only v	valid value for <i>idata</i> is 1)	
General Form	Function		
SAL reg,idata	Shift register reg left arithmetically by idata b	pit positions	
SAL mem,idata	Shift memory location mem left arithmetically	y by <i>idata</i> bit positions	
SAL <i>reg</i> ,CL	Shift register reg left arithmetically by CL bit	positions	
SAL mem,CL	Shift memory location mem left arithmetically	y by CL bit positions	
Example			
SAL BL,1	Shift BL left arithmetically by 1 bit position		
SAL VAR,1	Shift memory location VAR left arithmetically by 1 bit position		
SAL DX,CL	Shift DX left arithmetically by CL bit positions		

SAR	Shift right arithmetic       O D I T S Z A P         * * * ? *		
<b>Description</b> : This instruction shifts the destination operand right arithmetically by the specified number of bit positions. The value of the sign bit is replicated to the next lower bit positions, and the low order bits of the destination value are lost. (Note: on processors prior to the 80386, the only valid value for <i>idata</i> is 1)			
General Form	Function		
SAR reg,idata	Shift register reg right arithmetically by idata bit positions		
SAR mem,idata	Shift memory location mem right arithmetically by idata bit position	าร	
SAR <i>reg</i> ,CL	Shift register reg right arithmetically by CL bit positions		
SAR <i>mem</i> ,CL	Shift memory location <i>mem</i> right arithmetically by CL bit positions		
Example			
SAR BL,1	Shift BL right arithmetically by 1 bit position		
SAR VAR,1	Shift memory location VAR right arithmetically by 1 bit position		
SAR DX,CL	Shift DX right arithmetically by CL bit positions		

SBB	Subtract with borrow       ODITSZAP         * * * * *		
<b>Description</b> : This instruction subtracts the source operand and the current value of the carry flag from the destination operand. This instruction treats the carry flag as a borrow flag from a previous subtraction.			
General Form	Function		
SBB reg,idata	Subtract idata with borrow from register reg		
SBB mem,idata	Subtract idata with borrow from memory loc	ation <i>mem</i>	
SBB regd, regs	Subtract register regd with borrow from regi	ster <i>regs</i>	
SBB reg,mem	Subtract memory location mem from register	er <i>reg</i>	
SBB mem,reg	Subtract register reg from memory location mem		
Example	·		
SBB AX,CX	Subtract with borrow CX from AX		
SBB VAR,DX	Subtract with borrow DX from memory location VAR		
SBB BL,VAR	Subtract with borrow memory location VAR from BL		

SCAS	Scan string	0 D I T S Z A P C * * * * * *
memory location specifi comparison and the cor size of the operand is a if the direction flag is se	es the value in the accumulator (AL, AX or EA ed by ES:DI (or ES:EDI). The flags are set ac ntents of the DI (EDI) register is adjusted by th dded to DI (EDI) if the direction flag is clear a et. EPE, REPZ, REPNE, REPNZ) can be used v	ccording to the results of the ne size of the operand. The and subtracted from DI (EDI)
it to be repeated.	EFE, REFZ, REFINE, REFINZ) can be used v	
General Form	Function	
SCASB	Scan string byte	
SCASW	Scan string word	
SCASD	Scan string double word (80386 or later)	
Example	· · · · · · · · · · · · · · · · · · ·	
SCASB	Compare AL with the byte at ES:DI, set	flags, adjust DI by 1
SCASW	Compare AX with the word at ES:DI, set	flags adjust DI by 2

SETcc	Set byte on <i>condition</i> (80386 or later)	0 -	D -	I -	Т -	S -	Z -	A -	P -	C -
Description:										
General Form	Function									
Example										

SGDT	Store global descriptor table register (80286 or later)	0 D I T S Z A P C 
Description:		
General Form	Function	
General Form	Function	
Example		

SHL	Shift left logical	0 D I T S Z A P C * * * ? * *	
Description:			
This instruction shifts the destination operand left logically by the specified number of bit positions. The low order bit positions of the destination are set to 0. The high order bits shifted out of the destination are lost. The arithmetic shift left (SAL) and logical shift left (SHL) are equivalent operations. (Note: on processors prior to the 80386, the only valid value for <i>idata</i> is 1)			
General Form	Function		
SHL reg,idata	Shift register reg by idata bit positions		
SHL mem,idata	Shift memory location mem left by idata bit	positions	
SHL reg,CL	Shift register <i>reg</i> left by CL bit positions		
SHL mem,CL	Shift memory location mem left by CL bit po	ositions	
Example			
SHL BL,1	Shift BL left by 1 bit position		
SHL VAR,1	Shift memory location VAR left by 1 bit pos	ition	
SHL DX,CL	Shift DX left by CL bit positions		

SHLD	Shift double operand left logical (80386 or later)	0 D I T S Z A P C * * * ? * *
Description:		
General Form	Function	
Example		

SHR	Shift right logical	0 D I T S Z A P C * * * ? * *		
<b>Description</b> : This instruction shifts the destination operand right logically by the specified number of bit positions. The high order bit positions of the destination are set to 0. The low order bits shifted out of the destination are lost. (Note: on processors prior to the 80386, the only valid value for <i>idata</i> is 1)				
General Form	Function			
SHR reg,idata SHR mem,idata SHR reg,CL SHR mem,CL	Shift register <i>reg</i> right by <i>idata</i> bit positions Shift memory location <i>mem</i> right by <i>idata</i> bit Shift register <i>reg</i> right by CL bit positions Shift memory location <i>mem</i> right by CL bit po			
Example				
SHR BL,1 SHR VAR,1	Shift BL right by 1 bit position Shift memory location VAR right by 1 bit position	ition		
SHR DX,CL	Shift DX right by CL bit positions			

SHRD	Shift double operand right logical (80386 or later)	0 D I T S Z A P C * * * ? * *
Description:		
General Form	Function	
Example		

SIDT	Store interrupt descriptor table register (80286 or later)	0 D I T S Z A P C 
Description:		
General Form	Function	
Example		

Store local descriptor table register (80286 or later)	0 D I T S Z A P C 
Function	
	(80286 or later)

SMSW	Store machine status word (80286 or later)	0 D I T S Z A P C 
Description:		
General Form	Function	
Example		

STC	Set carry flag	0 D I T S Z A P C 1
Description:		
This instruction will set	the carry flag, CF, to 1.	
General Form	Function	
STC	Set the carry flag	
Example		
STC	Set the carry flag	

STD	Set direction flag	0 D I T S Z A P C - 1
Description:		
This instruction will s	et the direction flag, DF, to 1. This setting c	auses string instructions to
decrement the pointe	er registers.	-
General Form	Function	
STD	Set the direction flag to 1	
Example		
STD	Set the direction flag to 1	

STI	Set interrupt flag	0 D I T S Z A P C 1
Description:		
This instruction will set	the interrupt flag. When the interrupt flag is	s set, the processor will respond
to interrupt requests.		
General Form	Function	
STI	Set the interrupt flag	
Example		
STI	Set the interrupt flag	

STOS	Store string	0 D I T S Z A P C 	
Description:			
specified by ES:DI (ES:EI	This instruction will write the contents of the accumulator (AL, AX or EAX) to the memory location specified by ES:DI (ES:EDI for 32 bit operations). It then adjusts DI (EDI) according to the size of		
	etting of the direction flag. The operand size is subtracted from DI (EDI) if the direction flag		
	be used with this instruction to cause it to be	repeated.	
General Form	Function		
STOSB	Store string byte		
STOSW	Store string word		
STOSD	Store string double word (80386 and later)		
Example	· · · · · · · · · · · · · · · · · · ·		
STOSB	Store contents of AL at memory location E	S:DI and adjust DI by 1	
STOSW	Store contents of AX at memory location E	S:DI and adjust DI by 2	

STR	Store task register (80286 or later)	0 D I T S Z A P C 
Description:		
General Form	Function	
Example		

SUB	Subtract borrow	0 D I T S Z A P C * * * * * *
Description:		
This instruction subtracts	he source operand from the destination operand	I. This instruction treats
the carry flag as a borrow	flag and will set the carry flag if a borrow occurs	
General Form	Function	
SUB reg,idata	Subtract idata from register reg	
SUB mem,idata	Subtract idata from memory location mem	
SUB regd, regs	Subtract register regd from register regs	
SUB reg,mem	Subtract memory location <i>mem</i> from register	reg
SUB mem, reg	Subtract register reg from memory location m	nem
Example	·	
SUB AX,CX	Subtract CX from AX	
SUB VAR,DX	Subtract DX from memory location VAR	
SUB BL,VAR	Subtract memory location VAR from BL	

TEST	Test bits	O D I T S Z A P C 0 * * ? * 0
Description:		
	perform a logical comparison of the bits in the	
contents of the source and	destination registers are bitwise ANDed. The	result of the AND
operation is discarded and	the flags are set according to the logical resu	It of the AND.
General Form	Function	
TEST reg,idata	Bitwise and register reg with idata and set the	he flags
TEST mem,idata	Bitwise and memory location mem with idat	a and set the flags
TEST regd, regs	Bitwise and register regd with register regs	and set the flags
TEST reg,mem	Bitwise and register reg with memory location	on mem and set the flags
TEST mem, reg	Bitwise and memory location mem with regi	ister reg and set the flags
Example		
TEST AL,3Fh	AND the contents of AL with 3Fh and set the	e flags
TEST AX,DX	AND the contents of AX with DX and set the	e flags
TEST VAR,01h	AND the contents of memory location VAR	with 01h and set flags

VERR	Verify read access (80286 or later)	0 D I T S Z A P C *
Description:		
General Form	Function	
Example		

VERW	Verify write access (80286 or later)	0 D I T S Z A P C *
Description:		
General Form	Function	
Example	•	

WAIT	Wait until not busy	0 D I T S Z A P C 
Description:		
This instruction cau	uses the processor to go into an idle state until t	he BUSY pin goes to an
inactive state. It is	normally used to synchronize the main processo	or with a coprocessor such as

inactive state. It is normally used to synchronize the main processor with a coprocessor such as the math coprocessor (8087). This instruction should be used after floating point coprocessor instructions to ensure that the coprocessor instruction has completed prior to accessing the result.

General Form	Function
WAIT	Wait for coprocessor not busy
Example	
WAIT	
WAII	

WBINVD	Write and invalidate cache (80486 or later)	0 D I T S Z A P C 
Description:		
General Form	Function	
Example		

XADD	Exchange and add (80486 or later)	0 D I T S Z A P C * * * * * *
Description:		
General Form	Function	
Example		

XCHG	Exchange	0 D I T S Z A P C
Description:		
This instruction will exc	hange the contents of the two operands.	
General Form	Function	
XCHG regd, regs	Exchange the contents of register regd with register regs	
XCHG reg,mem	Exchange the contents of register reg with	memory location mem
XCHG mem,reg	Exchange the contents of memory location mem with register reg	
Example		
XCHG AX,DX	Exchange the contents of AX with DX	
XCHG VAR,CL	Exchange the contents of CL with memory	location VAR

XLAT	Translate using table	0 D I T S Z A P C 
Description:		
This instruction uses the contents of AL as an index into a table located at the memory location		
specified by DS:BX (DS:EBX for 32 bit operation). The contents of AL is replaced by the byte at		
the indexed locat	ion in the table.	

General Form	Function
XLAT	Translate using table
Example	
XLAT	Translate AL using table at DS:BX

XOR	Logical exclusive OR	0 D I T S Z A P C 0 * * ? * 0
Description:		
This instruction performs a logical exclusive or operation between each bit of the source operand		
and each bit of the destination operand. The result is stored in the destination.		
General Form Function		
XOR reg,idata	Logical XOR reg with idata	
XOR mem,idata	Logical XOR contents of memory location mem with idata	
XOR regd, regs	Logical XOR regd with regs	
XOR reg,mem	Logical XOR reg with contents of memory location mem	
XOR mem,reg	Logical XOR contents of memory location mem with reg	
Examples		
XOR AL,07FH	Inverts all but the high bit of AL	
XOR DATA3,DX	Logical XOR of word at memory location	
XOR CL,ES:[DI+2]	Logical XOR of byte at memory location I	ES:DI+2 with CL
XOR BX,CX	Logical XOR of BX with CX	
XOR AX,MASK[SI]	Logical XOR of word at memory location	DS:MASK+SI with AX

**Revision History:** 09/05/2001 (GeneA): Initial version completed 09/10/2001 (GeneA); Corrected error in example to MOV instruction
